**Systems-Thinking**: Study of a system to find the nature of interdependencies. What happens when one element of a system changes? How do the parts influence each other? The distinction between a “system” and a “heap” is the interdependent links between elements. If you take an element out of a heap, it doesn’t have an impact. If you take an element out of a system, it impacts at least one other element of the system.

**How will Systems-Thinking skills help our students?**

Since our first Earth Day 33 years ago, teachers have sought ways to nurture civic engagement skills regarding environmental issues. Our future depends on the next generation’s ability to make informed decisions and engage in “Earth Citizen” policy-making efforts for a sustainable future, both for themselves and for their children. District-by-district efforts towards greening buildings, increasing recycling, reducing waste, and teaching environmental literacy are all incredible accomplishments, given teachers’ time and resources for these endeavors.

However, to optimize outcomes from these environmentally-minded commitments, students need sophisticated skills to identify the complex systems we all engage in, and identify how a change to one element of a system impacts the remaining elements. This way of expanding our thinking is called **Systems Thinking**. At an elementary grade level, exercising this skill can be easily incorporated into ELA reading and writing. As a science tool, it supports Science standards for scientific reasoning.

The field of Systems-Thinking Modeling is most often associated with organizational transformation, and as an analytical business tool that requires extremely complex modeling and representational skills. This CELF handout is simply an introductory guide to the potential application and benefit of systems thinking skills for our next generation of decision makers. Although an educational pedagogy for Systems Thinking Modeling is still being developed, it is increasingly viewed as a way to realize the full educational benefit of environmental literacy by putting that content in the context of changing systems, while also engaging students in the 12 **Big Ideas of Education for Sustainability**. In order to create and live in a sustainable future, students benefit from a meaningful understanding of the following Big Ideas of Education for Sustainability concepts: **Community, Systems, Diversity, Interdependence, Cycles, Change Over Time, Limits, Long-Term Effects** and **Equilibrium**. Student understanding and application of **Fairness/Equity, Place, and Ability to Make a Difference** are demonstrated as a result of experience with systems-thinking.

**As a resource for ELA connections to Systems-Thinking**, we recommend [When a Butterfly Sneezes](https://www.celfeducation.org/library/when-a-butterfly-sneezes), by Linda Booth Sweeney, who created several system-thinking professional development tools for both educators and corporate leaders. Linda realized that elementary ELA standards offer a rich opportunity for foundational exposure to systems thinking. The title of her book refers to “the butterfly effect” – how a small change to an initial condition can affect large complex systems.

**Tendency towards Linear story-telling**: In the primary grades, supporting student story retelling and sequencing skills reinforce the use of “first, then, next, finally” and steers students towards linear storytelling and comprehension. L.B. Sweeney recognized that many children’s picture books that appear linear on one level, can provide practice, not only in identifying a system, but in examining impacts within the system.
The Web of Life Activity: An ideal introduction for students to see interconnections and understand unanticipated consequences is through the Web of Life activity. Students discover interdependencies of system elements. You can find instructions for this 15 minute activity here: http://forces.si.edu/main/pdf/PreK-1-WebofLife.pdf. This activity can be used in alignment with NYC Scope and Sequence and CCLS ELA standards (see next page). A Youtube video demonstrating the game is found here: http://www.youtube.com/watch?v=Fivc08jK2OE.

Experience identifying a System: There are many gateways for students to gain experience identifying systems. A family, school and community are all systems rather than heaps. A heap is a set of elements that are unchanged when one element is removed. (E.g., taking a pair of shoes out of your shoe closet doesn’t change the remaining shoes.) Reviewing just one web of life in a natural system will give students a visual template to create models of other systems. From p.151 of Dr. Art’s Guide to Science: “All the different ecosystems have a similar pattern of organization. They all require a source of energy and a group of organisms that can capture that energy and store it in chemical form. For the vast majority of ecosystems, the sun provides the energy. Plant life, ranging from microscopic algae to towering redwood trees, captures the energy in sunlight and stores it as chemical energy in sugar molecules.” Ecosystem Organisms: Producers, Herbivores, Carnivores and Decomposers.

Photo of pyramids from Dr. Art’s Guide to Science, p.237. (Note the size of the producer in this pyramid, and what happens when the producer is impacted.)
**Systems Modeling:** Creating Food Webs and pyramids are one type of model that shows relationships between parts. **Systems Modeling** goes beyond identifying relationships – systems modeling shows the impact and behavior—**WHAT HAPPENS** --between elements within a system.

**WHO (World Health Organization) had not done Systems Modeling:** The Day They Parachuted Cats on Borneo
The Language of Systems-Thinking

Studying food webs and food chains within identified ecosystems helps students learn the elements of a system, but what happens to the food web when one or more elements is changed? Students can answer this question by using the language of systems thinking, creating a Causal Loop Diagram (CLD), “lowering the water line, and seeing the whole iceberg rather than just the tip.”

**FEEDBACK LOOPS DESCRIBE TWO WAYS IN WHICH SYSTEM COMPONENTS WORK.**

**Balancing Feedback Loops:** (Hawks/mice) elements tend to stay in balance throughout the loop. System resets itself to balance.

**Reinforcing Feedback Loops:** a change in one direction continues the change in that direction. (E.g., introducing rabbits into a system without predators leads to a rabbit population explosion.)

**Stock:** An accumulation of material or information that has built up in a system over time.

**Flow:** Material or information that enters or leaves a stock over a period of time.

**SYSTEMS ARCHETYPES**

**Fixes that Fail:** quick and easy solutions often make a situation worse

**Limits to Success:** time horizons and delays result in actuated limits (e.g., a flooded market)

**Tragedy of the Commons:** cumulative effect of individual actions (e.g., pollution, littering)

**Shifting the Burden:** taking action to treat the symptom without solving the initial problem (e.g., borrowing more money to cover overspending)

**Escalation:** reinforcing loop based on two elements’ mutually increasing actions.

**Causal Loop Diagram Symbols**

- **R** Reinforcing feedback loop
- **B** Balancing feedback loop
- **S** Causal link where X adds to Y or X causes a change in Y in the same direction.
- **O** Causal link between two variables where X subtracts from Y or X causes a change in Y in the opposite direction.

P.3. According to the Merriam-Webster dictionary, the “butterfly effect” is a property of chaotic systems by which small changes in initial conditions can lead to large-scale and unpredictable variation in the future state of the system.

This is not a complete list of terms, archetypes or diagrams used in Systems-Thinking and modeling. Consider this partial list an introduction. For more information, see the resources listed in this packet.
